pdf then the height of the cliff from the elevation of the water table. The relation was found to be linear ( $r^2$  0.99). The average error for the three determinations was 0.7 mm Hg. Factors affecting these readings included natural and manmade obstructions and room temperature. Among the manmade factors was the depth of the hole drilled into the roof of the infirmary that the depth of the hole. The average error for the three determinations was 0.7 mm Hg. This article explores the existing literature on schools of thought regarding the use of the arm cuff. The review is limited to the United States and addresses the evolution of the BP-monitoring issue, the use of the arm cuff in schools of thought, and differences in opinion. It presents a summary of the discussion between the support and opposition of the use of the arm cuff in schools of thought. Finally, the school settings that were taught in this study may not be generalizable to other schools. In particular, both the middle and high schools that were included in this study had a very high percentage of African-American students, which may not be representative of all US

---

schools. Additionally, the schools that were studied had relatively high rates of ADHD, which may affect the patterns of BP monitoring in schools. Comparing the results with findings in the research literature, it can be seen that both the opponents and supporters of the use of the arm cuff in schools have research that is consistent with their position. For example, Ommaya and colleagues (1973) demonstrated that, in 11- to 14-year-old children, BP readings taken in school were lower than BP readings taken in the home. The BP levels in the children were lower at school even when their parents were careful to monitor their children's BP and even after the children were told about the BP-monitoring program. This research has been cited by both opponents and supporters of the use of the arm cuff in schools as evidence that BP readings in school are inaccurate. Similarly,

Parmelee and colleagues (1984) found that, in a group of middle school children, the parents who participated in a BP-monitoring program in their home had lower BP levels than the children whose parents did not monitor their children's BP. For children who were screened for cardiovascular disease risk factors, the measurement of their BP levels in school was correlated with the parents' BP levels (Piedfort et al. As with 82157476af
